## Methods for making buffers

**NC State University**

# Two ways to make a buffer

## Method 1

Add the acid and conjugate base to the solution in a defined proportion.

## Method 2

Add a strong acid to the weak base (or vice versa) until the desired proportion  $[\text{A}^-]/[\text{HA}]$  is obtained.

# Buffer strength

The ratio  $[A^-]/[HA]$  should be as close as possible 1:1, but the amounts may vary. To make a stronger buffer you simply need to increase the amount of each component. Let's investigate.

Suppose we add 1 mL of 1 M HCl to 1 liter of solution. The final concentration of HCl is 0.001 M.

# Buffer strength

The ratio  $[A^-]/[HA]$  should be as close as possible 1:1, but the amounts may vary. To make a stronger buffer you simply need to increase the amount of each component. Let's investigate.

Suppose we add 1 mL of 1 M HCl to 1 liter of solution. The final concentration of HCl is 0.001 M.  $\text{pH} = 3$

# Buffer strength

The ratio  $[A^-]/[HA]$  should be as close as possible 1:1, but the amounts may vary. To make a stronger buffer you simply need to increase the amount of each component. Let's investigate.

Suppose we add 1 mL of 1 M HCl to 1 liter of solution. The final concentration of HCl is 0.001 M.  $\text{pH} = 3$

Suppose we add 1 mL of 1 M HCl to 1 liter of 10 mM optimal phosphate buffer solution ( $\text{pK}_a = 7.2$ ) solution. The final concentration of HCl is 0.001 M.  $\text{pH} = \text{pK}_a + \log_{10}([A^-]/[HA])$

# Buffer strength

Keeping in mind that the unbuffered solution in this example ( $[\text{HCl}] = 0.001 \text{ M}$ ) would be  $\text{pH} = 3$

Suppose we add 1 mL of 1 M HCl to 1 liter of 10 mM optimal phosphate buffer solution ( $\text{pK}_a = 7.2$ ) solution. The final concentration of HCl is 0.001 M.

$$\text{pH} = \text{pK}_a + \log_{10}([\text{A}^-]/[\text{HA}])$$

$$[\text{A}^-] = 0.005 - 0.001 = 0.004 \quad [\text{HA}] = 0.005 + 0.001 = 0.006$$

$$\text{pH} = 7.2 + \log_{10}(0.004/0.006) = 7.02$$

If the target  $\text{pH} = 7.2$  (i.e.  $\text{pH} = \text{pK}_a$ ) then this buffer is too weak. An error of 0.2 pH units could be significant.

# Buffer strength

Keeping in mind that the unbuffered solution in this example ( $[\text{HCl}] = 0.001 \text{ M}$ ) would be  $\text{pH} = 3$

Suppose we add 1 mL of 1 M HCl to 1 liter of 100 mM optimal phosphate buffer solution ( $\text{pK}_a = 7.2$ ) solution. The final concentration of HCl is 0.001 M.

$$\text{pH} = \text{pK}_a + \log_{10}([\text{A}^-]/[\text{HA}])$$

$$[\text{A}^-] = 0.05 - 0.001 = 0.049 \quad [\text{HA}] = 0.05 + 0.001 = 0.051$$

$$\text{pH} = 7.2 + \log_{10}(0.049/0.051) = 7.18$$

If the target  $\text{pH} = 7.2$  (i.e.  $\text{pH} = \text{pK}_a$ ) then this buffer is reasonable. The difference is only -0.02.

# Buffer strength

Keeping in mind that the unbuffered solution in this example ( $[\text{HCl}] = 0.001 \text{ M}$ ) would be  $\text{pH} = 3$

Suppose we add 1 mL of 1 M HCl to 1 liter of 300 mM optimal phosphate buffer solution ( $\text{pK}_a = 7.2$ ) solution. The final concentration of HCl is 0.001 M.

$$\text{pH} = \text{pK}_a + \log_{10}([\text{A}^-]/[\text{HA}])$$

$$[\text{A}^-] = 0.150 - 0.001 = 0.149 \quad [\text{HA}] = 0.150 + 0.001 = 0.151$$

$$\text{pH} = 7.2 + \log_{10}(0.149/0.151) = 7.194$$

If the target  $\text{pH} = 7.2$  (i.e.  $\text{pH} = \text{pK}_a$ ) then we would say that this buffer is definitely strong enough, difference = -0.006

# Titrating to make a buffer

You can create a buffer either by adding the acid and its conjugate base to a solution or by titrating in strong base to acid (or vice versa). Remember, regardless of the method used to prepare it:

The buffering strength is maximum when  $[HA] = [A^-]$

The buffering range is considered to extend from  $[A^-]/[HA] = 0.1$  to  $[A^-]/[HA] = 10$ . This is subjective. Wertz suggests 0.01 to 100 is an acceptable range.
