$$
\begin{aligned}
& \text { Cement production } \\
& \mathrm{CaCO}_{3}=\mathrm{CaO}+\mathrm{CO}_{2}
\end{aligned}
$$

$6 \%$ of the world's $\mathrm{CO}_{2}$ comes from cement factories.

Assuming 840 million tons of $\mathrm{CO}_{2}$ gas are emitted each year from cement factories, what mass of $\mathrm{CaCO}_{3}$ is consumed to make cement?

$$
\mathrm{CaCO}_{3}=\mathrm{CaO}+\mathrm{CO}_{2}
$$

Assuming 840 million tons of $\mathrm{CO}_{2}$ gas are emitted Each year from cement factors, what mass of $\mathrm{CaCO}_{3}$ is consumed to make cement?

$$
\mathrm{CaCO}_{3}=\mathrm{CaO}+\mathrm{CO}_{2}
$$

Solution: Step 1.The stoichiometry is easy here.
It is $1: 1$. So we can get the number of moles of $\mathrm{CO}_{2}$,

$$
n_{\mathrm{CO}_{2}}=\frac{840 \times 10^{12} \mathrm{grams}}{44 \mathrm{grams} / \mathrm{mole}}
$$

which is $1.9 \times 10^{13}$ moles.

Assuming 840 million tons of $\mathrm{CO}_{2}$ gas are emitted each year from cement factors, what mass of $\mathrm{CaCO}_{3}$ is consumed to make cement?

$$
\mathrm{CaCO}_{3}=\mathrm{CaO}+\mathrm{CO}_{2}
$$

Solution: Step 1.The stoichiometry is easy here.
It is $1: 1$. So we can get the number of moles of $\mathrm{CO}_{2}$.

$$
n_{\mathrm{CO}_{2}}=\frac{840 \times 10^{12} \mathrm{grams}}{44 \mathrm{grams} / \mathrm{mole}}
$$

Step 2. Now we calculate the mass of of $\mathrm{CaCO}_{3}$.

$$
m_{\text {CaCo }_{3}}=\left(1.9 \times \times 10^{13} \mathrm{moles}\right)(100 \mathrm{grams} / \mathrm{mol})
$$

The answer is $1.9 \times 10^{15}$ grams or 1.9 billion tons.
